

# CSC3100 Data Structures Lecture 3: Array

Yixiang Fang
School of Data Science (SDS)
The Chinese University of Hong Kong, Shenzhen

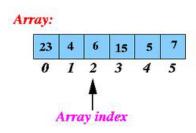

- Overview
- Concepts of arrays
- ADT of Arrays
- Implementation
- Examples

- Arrays are among the oldest and most important data structures
  - Arrays are supported by almost every programming language
  - Arrays are used for representing vectors/matrices
  - The simplest type of array is a linear array, or onedimensional array

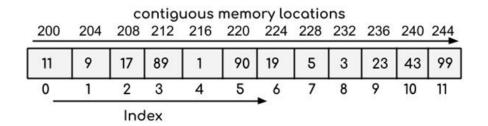

- An array stores the same type of objects together, and access the objects by their indices
- Pro & Con of arrays:
  - Pro: If you know the index (where), you can find the object (content) with one basic operation (efficient); Efficient search if array is sorted
  - Con: If you insert an object in a place between two objects in an array, you have to move the objects first;
     The capacity is fixed

- The individual values in an array are called elements; all the elements must be of the same type
- The number of elements is called the length of the array, which is fixed when the array is created
- ▶ Each element is identified by its position in the array, which is called index (In C/C++/Java, the index numbers begin with 0)
- An array is a linear data structure that hosts a collection of data types stored at consecutive locations in a computer's memory
  - The memory address of the first element of an array is called first address, foundation address, or base address
  - The memory position of each element can be computed from its index

# Array ADT

```
ADT Array
Array createArray(n)
Item retrieve(arr, i)
Item store(arr, i, itemToStore)
```

- createArray(n)
  - $\circ$  Initialized an array of size n to store item
- retrieve(arr, i)
  - arr[i],
  - Return the item stored in the i-th position of the array
- store(arr, i, itemToStore)
  - Store itemToStore to the i-th position of the array
  - arr[i] = itemToStore

# Advantage of ADT

- We can design algorithms without knowing its underlying implementation
  - E.g., design a linear search algorithm with an array using ADT

### Algorithm 1: Linear Search

Input: An array a of integers with length n, an integer searchnum Output: the index i such that the value stored in the i-th position equals searchnum, or -1 if no such i exists

```
int i;
for (i=0; i<n; i++){
    if( retrieve(a,i) == searchnum )
        return i;
}
return -1;</pre>
```

# Array ADT: example

- We can design algorithms without knowing its underlying implementation
  - E.g., implement the dimension-product given two arrays  $a_1$  and  $a_2$  and output to  $a_3$  such that  $a_3[i] = a_1[i] \cdot a_2[i]$

### Java: array declaration

- An array is characterized by
  - Element type
  - Length: type[] identifier = new type[length];
- Default values in initialization

numerics0

boolean false

objectsnull

Elements of an array can be objects of any Java class

Example: An array of 5 instances of the student class Student [ ] topStudents = new Student[5];

### Java: array operations

Use named constant to declare the length of an array, or read the length of an array from the user private static final int N\_JUDGES = 5; double[] scores = new double[N\_JUDGES];

- Identifying an element by an integer number or an expression array[index], array[(a+b)/2]

# Array initialization

A convenient way of initializing an array:
 int[] digits = {0,1,2,3,4,5,6,7,8,9};
 String[] US CITIES\_OVER\_ONE\_MILLION = {
 "New York",
 "Los Angeles",
 "Chicago",
 "Huston",
 "Phoenix",
 "San Diego",
 "San Antonio",
 "Dallas",
 }
}

- Starting index numbering at 0 can be confusing, so we have two standard ways:
  - Use Java's index number internally, and then add one when presenting to the user
  - Use index values beginning at 1, and ignore the first (0) element in each array

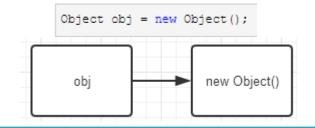

### Pass-by-Value vs Pass-by-Reference

```
swapElements(array[i], array[n - i - 1]) [wrong]
swapElements(array, i, n - i - 1)
private void swap(int[] array, int p1, int p2) {
    int tmp = array[p1];
    array[p1] = array[p2];
    array[p2] = tmp;
}
What is Pass-by-Value?
```

- The value of a function parameter is copied to another location of the memory
- When accessing or modifying the variable within the function, it accesses only the copy, so there is no effect on the original value
- What is Pass-by-Reference?
  - The memory address is passed to that function, so the function gets access to the actual variable

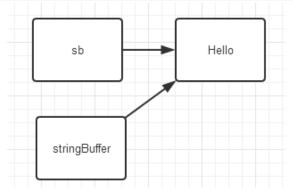

```
public class test {
    public static void main(String[] args) {
        int i = 1;
        System.out.println("before change, i = "+i);
        change(i);
        System.out.println("after change, i = "+i);
    }
    public static void change(int i) {
        i = 5;
    }
}
```

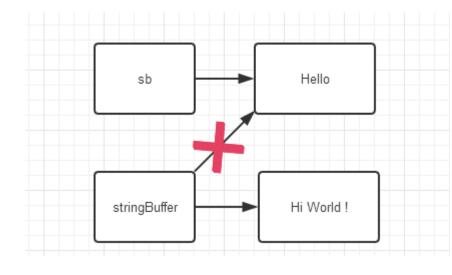

```
before change, i = 1
after change, i = 1
```

```
public class test {
   public static void main(String[] args) {
        StringBuffer sb = new StringBuffer("Hello ");
        System.out.println("before change, sb is "+sb.toString());
        change(sb);
        System.out.println("after change, sb is "+sb.toString());
   }
   public static void change(StringBuffer stringBuffer){
        stringBuffer.append("world !");
   }
}
```

before change, sb is Hello after change, sb is Hello world !

```
public class test {
    public static void main(String[] args) {
        StringBuffer sb = new StringBuffer("Hello ");
        System.out.println("before change, sb is "+sb.toString());
        change(sb);
        System.out.println("after change, sb is "+sb.toString());
}
    public static void change(StringBuffer stringBuffer){
        stringBuffer = new StringBuffer("Hi ");
        stringBuffer.append("world !");
}
```

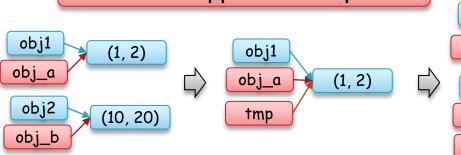

before change, sb is Hello after change, sb is Hello

```
1 - public class MyClass {
 1 → public class MyClass {
                                                  # obj a: x=10 y=20
                                                                                       public int x, y;
                                                                                                                                 # obj a: x=10 y=20
        public int x, y;
                                                                                3
                                                  # obj b: x=1 y=2
                                                                                                                                  # obj b: x=1 y=2
 3
                                                                                4 +
                                                                                       public MyClass(int a, int b){
 4 +
        public MyClass(int a, int b){
                                                                                5
                                                                                           x = a;
                                                  obj1: x=1 y=2
                                                                                                                                 obj1: x=10 y=20
 5
            x = a;
                                                                                6
                                                  obj2: x=10 y=20
                                                                                           y = b;
                                                                                                                                 obj2: x=1 y=2
 6
            y = b;
                                                                                7
 7
                                                                                8 +
                                                                                       public static void swap(MyClass obj a, MyClass obj b){
 8 +
        public static void swap(MyClass obj a, MyClass obj b){
                                                                                9
                                                                                           int tmp = obj_a.x;
 9
            MyClass tmp = obj a;
                                                                               10
                                                                                           obj a.x = obj b.x;
10
            obj a = obj b;
                                                                               11
                                                                                           obj b.x = tmp;
11
            obj b = tmp;
                                                                               12
12
                                                                               13
                                                                                           tmp = obj_a.y;
13
          System.out.println("# obj a: x=" + obj a.x + " y=" + obj a.y);
                                                                               14
                                                                                           obj a.y = obj b.y;
14
          System.out.println("# obj b: x=" + obj b.x + " y=" + obj b.y);
                                                                               15
                                                                                           obj b.y = tmp;
15
          System.out.println();
                                                                               16
16
                                                                               17
                                                                                         System.out.println("# obj a: x=" + obj a.x + " y=" + obj a.y);
17 -
        public static void main(String args[]) {
                                                                               18
                                                                                         System.out.println("# obj b: x=" + obj b.x + " y=" + obj b.y);
18
          MyClass obj1 = new MyClass(1, 2);
                                                                               19
                                                                                         System.out.println();
19
          MyClass obj2 = new MyClass(10, 20);
                                                                               20
20
                                                                               21 -
                                                                                       public static void main(String args[]) {
21
          MyClass.swap(obj1, obj2);
                                                                               22
                                                                                         MyClass obj1 = new MyClass(1, 2);
22
                                                                               23
                                                                                         MyClass obj2 = new MyClass(10, 20);
23
          System.out.println("obj1: x=" + obj1.x + " y=" + obj1.y);
                                                                               24
24
          System.out.println("obj2: x=" + obj2.x + " y=" + obj2.y);
                                                                               25
                                                                                         MyClass.swap(obj1, obj2);
25
                                                                               26
26 }
                                                                               27
                                                                                         System.out.println("obj1: x=" + obj1.x + " y=" + obj1.y);
                                                                               28
                                                                                         System.out.println("obj2: x=" + obj2.x + " y=" + obj2.y);
                                                                               29
```

obj\_b

### What happens in swap?

30 } obj1 obj1 (1, 2)(1, 2)tmp tmp obj\_b obj2 (10, 20)obj\_a obj2 (10, 20)obj\_a

15

### Exercise: using arrays

- Letter frequency table:
  - Given an array of letters,
     e.g., A[]={'A', 'B', 'C', 'B', 'A'}
     How to count the frequency of each letter efficiently?
- How to use an array to store a set of elements whose size is larger than the maximum number of elements in Java array?
  - Note that the maximum number of elements in a Java array is Integer.MAX\_VALUE

### Two-dimensional arrays

- Each element of an array is an array (of the same dimension)
  - E.g., a 3-by-2 matrix
     int[][] A = new int[3][2];
     int A[3][2] = { {1, 4}, {2, 5}, {3, 6}};
- An array of three arrays of dimension two

```
A[0][0] A[0][1]
A[1][0] A[1][1]
A[2][0] A[2][0]
```

### The ArrayList class

- The java.util package has a class called ArrayList
  - Provide standard array behaviors along with other useful operations
  - ArrayList is a Java class rather than a special form in the language
- All operations on ArrayLists are indicated using method calls
  - Create a new ArrayList by calling ArrayList constructor
  - Get the number of elements by calling the size method
  - Use the get and set methods to select individual elements

# More examples in Java

- Number arrays
  - int, float, double, ...
- String arrays
- Boolean arrays

```
public class Main
        public static void main(String[] args)
            // create an array
            int[] age = {12, 4, 5};
            // loop through the array
 8
            // using for loop
            System.out.println("Using for-each Loop:");
10
            for(int a : age)
11
12
                System.out.println(a);
13
14
15
```

### Output

```
Using for-each Loop:
12
4
5
```

```
public class Main
        public static void main(String[] args)
            int[] numbers = {2, -9, 0, 5, 12, -25, 22, 9, 8, 12};
            int sum = 0;
            Double average;
10
            // access all elements using for each loop
11
            // add each element in sum
            for (int number : numbers)
12
13
14
                 sum += number;
15
16
17
            // get the total number of elements
18
            int arrayLength = numbers.length;
19
20
            // calculate the average
            // convert the average from int to double
21
22
            average = ((double)sum / (double)arrayLength);
23
24
            System.out.println("Sum = " + sum);
25
            System.out.println("Average = " + average);
26
27
```

### Output:

```
Sum = 36
Average = 3.6
```

```

# Examples: String array

- String array is an array holding a fixed number of strings or string values
  - One structure commonly used in Java
  - Even the arguments of the Java 'main' function is a String Array
    - public static void main(String args[]){...}
- String array is an array of String objects
  - Each string is an object!

```
public class Main
        public static void main(String[] args)
            String[] myarray; //declaration of string array without size
            String[] strArray = new String[5]; //declaration with size
            //System.out.println(myarray[0]); //variable myarray might not have been initialized
10
            //display elements of second array
            System.out.print(strArray[0] + " " + strArray[1] + " " + strArray[2] + " " +
11
12
                             strArray[3] + " " + strArray[4]);
13
```

### null null null null null

```
import java.util.*;
    public class Main
        public static void main(String[] args)
 6
            //original array
 8
            String[] colorsArray = {"Red", "Green", "Blue" };
            System.out.println("Original Array: " + Arrays.toString(colorsArray));
10
11
            //length of original array
12
             int orig length = colorsArray.length;
13
14
            String newElement = "Orange";
15
            //define new array with length more than the original array
            String[] newArray = new String[ orig_length + 1 ];
16
17
18
            for (int i = 0; i < colorsArray.length; i++)</pre>
19
20
                 newArray[i] = colorsArray [i];
21

 9
             String searchStr = "Pen";
10
             for (int i = 0; i < strArray.length; i++)</pre>
11
                 if(searchStr.equals(strArray[i]))
12
13
14
                     index = i;
15
                     found = true;
16
                     break;
17
18
             if(found)
19
20
                 System.out.println(searchStr + " found at the index " + index);
             else
21
22
                 System.out.println(searchStr + " not found in the array");
23
24
```

Pen found at the index 4

```
import java.util.*;
    public class Main
 4 ▼ {
        public static void main( String[] args )
 6 ▼
            //string arrya declaration
            String [] str_Array = {"10", "20", "30", "40", "50"};
 8
            //print the string array
10
            System.out.println("Original String Array:");
            for(String val : str_Array)
11
                System.out.print(val + " ");
12
13
14
            System.out.println("\nThe integer array obtained from string array:");
15
            //declare an int array
            int [] int_Array = new int [str_Array.length];
16
17
18
            for(int i = 0; i < str Array.length; i++)</pre>
19
20
                 int_Array[i] = Integer.parseInt(str_Array[i]);
21
22
            //display the int array
23
            System.out.println(Arrays.toString(int_Array));
24
25
```

```
Original String Array:

10 20 30 40 50

The integer array obtained from string array:

[10, 20, 30, 40, 50]
```

# Examples: Boolean array

Each element of array is a Boolean value (true, false)

```
import java.util.Arrays;
    public class BooleanArrayTest
            public static void main(String[] args)
                   Boolean[] boolArray = new Boolean[5]; // initialize a boolean array
                   for(int i = 0; i < boolArray.length; i++)</pre>
                          System.out.println(boolArray[i]);
10
11
12
                   Arrays.fill(boolArray, Boolean.FALSE);
13
                   // all the values will be false
14
                   for(int i = 0; i < boolArray.length; i++)</pre>
15
                          System.out.println(boolArray[i]);
17
19
                   Arrays.fill(boolArray, Boolean.TRUE);
20
21
                   for (int i = 0; i < boolArray.length; i++)</pre>
22
23
                          System.out.println(boolArray[i]);
24
```
